### Synchronous Generator Subtransient Reactance Prediction

The sub-transient reactance of a generator set is used to calculate the maximum available short circuit current for selecting circuit breakers with adequate interrupting rating. Since nearly all of the generator impedance is reactance, addition of the DC component for the first few cycles may almost double the symmetrical value of current.

Abstract For synchronous 3 phase electrical generator machine design, the ability to predict the subtransient reactance of a particular machine design is of prime importance. The subtransient reactance has a significant impact on the magnitude of the fault currents generated within the machine during an event such as a 3 phase short-circuit.

The subtransient reactance is a transient effect that's directly related to the electromagnetic relationships between the various physical components of the generator. Although the resistance of the windings of a synchronous generator are generally negligible compared to their reactance, they do play a role in the decay rates of the transient currents in the form of L/R time constants.

First: No, transient and subtransient reactance is not the same. Sub-transient refers to the first few cycles after the load of a generator has changed, while transient refers to the period of normally a few seconds until the system has stabilised. Sub transient reactance The period immediately after a short circuit on the generator and lasting upto 2-3 cycles, is called sub transient period. The current during this period is highest and is determined by sub transient reactance. The value of sub transient reactance is about half of the leakage reactance.
