Joints are the location where bones come together. Many joints allow for movement between the bones. At these joints, the articulating surfaces of the adjacent bones can move smoothly against each other. However, the bones of other joints may be joined to each other by connective tissue or cartilage.

9.1 Classification of Joints - Anatomy and Physiology

Synovial joints are characterized by the presence of a joint cavity. The walls of this space are formed by the articular capsule, a fibrous connective tissue structure that is attached to each bone just outside the area of the bone's articulating surface. The bones of the joint articulate with each other within the joint cavity.

Where two bones meet, called the joint, the bone ends are covered with cartilage, also known as gristle. This cartilage is sturdy, elastic and spongy or compressible, and keeps the bones from moving against each other at the joint. The cells of this cartilage, called chondrocytes, are thought to be the longest living cells of the body.
